

Release Readiness Checklist — Mobile Trading App

To be run against the release candidate before go/no-go. Every unchecked item needs an explicit, written waiver from the QA lead to ship anyway — nothing gets silently skipped.

Functional

- ☐ Sign-up / KYC flow completes on both iOS and Android
- ☐ Login, logout, and session expiry all behave correctly (no silent "logged in but writes fail" state)
- ☐ Biometric login works, and the fallback (PIN/password) works when biometrics fail or are unavailable
- ☐ Deposit flow completes and reflects correctly in balance (sandbox)
- ☐ Withdrawal flow completes and reflects correctly in balance (sandbox)
- ☐ Orders can be placed, viewed, and cancelled; cancelled orders cannot still fill
- ☐ Rapid double-submission of an order does not create duplicate orders
- ☐ Balance and portfolio values match the backend ledger after a burst of activity (deposit → trade → trade → withdraw)
- ☐ Order amounts respect correct decimal precision/rounding for every supported asset
- ☐ Push notifications for order fills / price alerts are delivered and deep-link to the correct screen
- ☐ Top navigation renders all expected items and routes correctly on both platforms
- ☐ Layout holds (no clipped/overlapping controls) across the supported device/breakpoint matrix

Reliability / edge cases

- ☐ App behavior on connection loss mid-order is unambiguous to the user (clearly pending/failed/succeeded, never silent)
- ☐ App resumes correctly after being backgrounded mid-transaction
- ☐ Invalid/unknown deep links and routes fail gracefully, not with a crash or blank screen
- ☐ Broken/dead links across nav and content have been checked (App Store/Play Store links, support, legal)
- ☐ App handles a slow/degraded network without hanging indefinitely or showing stale data as if it were current

Security

- ☐ No auth tokens, balances, or personal data in plaintext logs
- ☐ No sensitive data cached unencrypted on-device
- ☐ Certificate pinning active and verified in the release build (not just debug)

- ☐ Session tokens expire and are invalidated server-side on logout
- ☐ Rate limiting / abuse protection confirmed on auth and order endpoints

Compliance

- ☐ App Store / Play Store financial-app disclosure and licensing requirements reviewed and satisfied
- ☐ Required legal/regulatory disclaimers present and correctly worded
- ☐ Age rating and content rating correctly set
- ☐ Privacy policy and data-handling disclosures match what the app actually does

Operational readiness

- ☐ Crash reporting (Crashlytics/Sentry) wired up and alerting the team
- ☐ A remote kill switch / feature flag exists to disable trading (or a specific order type) without requiring an emergency app-store resubmission
- ☐ Rollback plan for the backend/API exists and has been tested
- ☐ On-call / incident response owner identified for launch day and the following 48 hours
- ☐ Support team briefed on known limitations and how to escalate a funds-related report

Test evidence

- ☐ Full @regression suite green on the release candidate (or every failure explicitly triaged and waived)
- ☐ Device matrix run completed (top iOS versions + top Android OEM/OS combinations)
- ☐ Manual exploratory pass completed on the release candidate build specifically (not just an earlier build)
- ☐ Bug bash completed, all P1/P2 findings resolved or explicitly accepted

Sign-off

- ☐ QA lead sign-off
- ☐ Engineering lead sign-off
- ☐ Product/business sign-off (aware of any accepted risk/waivers)
